1 Introduction

Given the opportunity to review the design document and related smart contract source code of the RoofStacks protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About RoofStacks Protocol

RoofStacks protocol aims users to collect Move To Earn (MTE) points in real world with their phones by using the AR technology. After collecting the activity, users will be able to swap MTE points to Matic in the coin distribution web page. The basic information of the audited protocol is as follows:

Item	Description

• https://github.com/roofstacks/move-to-earn-event-smart-contracts (229d56f)

And here is the commit ID after all fixes for the issues found in the audit have been checked in.

• https://github.com/roofstacks/move-to-earn-event-smart-contracts (85011b0)

1.2 About PeckShield

PeckShield Inc. [7] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

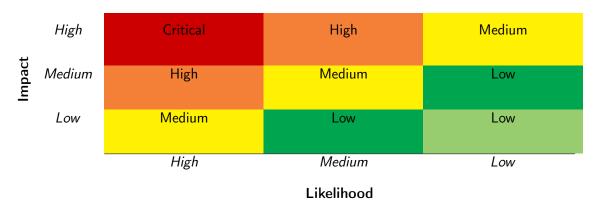

Table 1.2: Vulnerability Severity Classification

1.3 Methodology

To standardize the evaluation, we define the following terminology based on the OWASP Risk Rating Methodology [6]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild:
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a checklist of items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would

Table 1.3: The Full Audit Checklist

Category	Checklist Items		
	Constructor Mismatch		
	Ownership Takeover		
	Redundant Fallback Function

	Making Visibility Level Explicit		
	Making Type Inference Explicit		
	Adhering To Function Declaration Strictly		
	Following Other Best Practices		

additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [5], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings. Moreover, in case there is an issue that may affect an active protocol that has been deployed, the public version of this report may omit such issue, but will be amended with full details right after the affected protocol is upgraded with respective fixes.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary		
Configuration	Weaknesses in this category are typically introduced during		
	the configuration of the software.		
Data Processing Issues	Weaknesses in this category are typically found in functional-		
	ity that processes data.		
Numeric Errors	Weaknesses in this category are related to improper calcula-		
	tion or conversion of numbers.		
Security Features	Weaknesses in this category are concerned with topics like		
	authentication, access control, confidentiality, cryptography,		
	and privilege management. (Software security is not security		
	software.)		
Time and State	Weaknesses in this category are related to the improper man-		
	agement of time and state in an environment that supports		
	simultaneous or near-simultaneous computation by multiple		
5 C IV	systems, processes, or threads.		
Error Conditions,	Weaknesses in this category include weaknesses that occur if		
Return Values,	a function does not generate the correct return/status code,		
Status Codes	or if the application does not handle all possible return/status		
Describe Management	codes that could be generated by a function.		
Resource Management	Weaknesses in this category are related to improper management of system resources.		
Behavioral Issues	-		
Denavioral issues	Weaknesses in this category are related to unexpected behav-		
Business Logic	iors from code that an application uses.		
Dusilless Logic	Weaknesses in this category identify some of the underlying		
	problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can		
	be devastating to an entire application.		
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used		
mitialization and Cicanap	for initialization and breakdown.		
Arguments and Parameters	Weaknesses in this category are related to improper use of		
Barrieros aria i aramieses	arguments or parameters within function calls.		
Expression Issues	Weaknesses in this category are related to incorrectly written		
,	expressions within code.		
Coding Practices	Weaknesses in this category are related to coding practices		
3	that are deemed unsafe and increase the chances that an ex-		
	ploitable vulnerability will be present in the application. They		
	may not directly introduce a vulnerability, but indicate the		
	product has not been carefully developed or maintained.		

2 | Findings

2.1 Summary

Here is a summary of our findings after analyzing the implementation of the RoofStacks protocol. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	1	
Low	0	
Informational	1	
Total	2	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability and 1 informational recommendation.

Table 2.1: Key RoofStacks Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Medium	Trust Issue of Admin Keys	Security Features	Confirmed
PVE-002	Informational	Meaningful Events For Important States	Coding Practices	Fixed
		Change		

Besides the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 Detailed Results

3.1 Trust Issue of Admin Keys

• ID: PVE-001

Severity: Medium

• Likelihood: Low

• Impact: High

• Target: GoArtCampaign

• Category: Security Features [3]

CWE subcategory: CWE-287 [1]

Description

In the RoofStacks protocol, there is a privileged admin account that plays a critical role in governing and regulating the system-wide operations (e.g., system parameters setting and token withdraw). It also has the privilege to control or govern the flow of assets managed by this protocol. Our analysis shows that the privileged account needs to be scrutinized. In the following, we examine the privileged account and the related privileged accesses in current contracts.

To elaborate, we show below example privileged routines in the GoArtCampaign contract. These routines allow the admin account to add/remove admins, set contract state, swap collectible items to MATIC, etc.

```
80
     // register a new admin with the given wallet address
81
     function addAdmin(address _adminAddress) external onlyAdmin {
82
       // Can't add Ox address as an admin
83
       require(_adminAddress != address(0x0), '[RBAC] : Admin must be != than 0x0 address')
       // Can't add existing admin
85
       require(!isAdmin[_adminAddress], '[RBAC] : Admin already exists.');
86
       // Add admin to array of admins
87
       admins.push(_adminAddress);
88
       // Set mapping
89
       isAdmin[_adminAddress] = true;
90
91
92
     // remove an existing admin address
     function removeAdmin(address _adminAddress) external onlyAdmin {
```

```
94
95
      }
96
97
      // Set contract State as Active
98
      function setStateActive() external onlyAdmin {
99
       state = State.Active;
100
      }
101
102
      // Set contract State as Closed
103
      function setStateClosed() external onlyAdmin {
104
       state = State.Closed;
105
106
107
      // Change the contract's max reward amount
108
      function changeMaxReward(uint256 _maxReward) external onlyAdmin {
109
        maxRewardTotal = _maxReward;
110
111
112
      // change award ration
113
      function changeRatio(uint256 _ratio) external onlyAdmin {
114
      ratio = _ratio;
115
116
117
      // register a user's wallet address if the contract is in Active state.
118
      function registerWallet(address payable walletAddress, string memory userId)
119
       external
120
        onlyAdmin
121
      {
122
           . . .
123
      }
124
125
      // A user's collectible items can be swapped to MATIC through this function.
126
      {\tt function} \ \ {\tt swapCollectibleItemsToMatic(uint256} \ \ \_{\tt collectibleItemAmount, uint256}
          _participantIndex)
127
        external
128
       onlyAdmin
129
130
131
132
133
      134
          . . .
135
136
137
      // set service fee
138
      function setServiceFee(uint256 _fee) external onlyAdmin {
139
      fee = _fee;
140
141
142
      // set minimumAmount
143
      function setMinimumAmount(uint256 _minimumAmount) external onlyAdmin {
144
    minimumAmountToWithdraw = _minimumAmount;
```

It is worrisome if the privileged admin account is a plain EOA account. Note that a multi-sig account could greatly alleviate this concern, though it is still far from perfect. Specifically, a better approach is to eliminate the administration key concern by transferring the role to a community-governed DAO. In the meantime, a timelock-based mechanism can also be considered as mitigation.

Recommendation Promptly transfer the privileged account to the intended DAO-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status This issue has been confirmed.

3.2 Meaningful Events For Important States Change

• ID: PVE-002

Severity: Informational

Likelihood: N/A

• Impact: N/A

• Target: GoArtCampaign

Category: Coding Practices [4]

• CWE subcategory: CWE-563 [2]

Description

In Ethereum, the event is an indispensable part of a contract and is mainly used to record a variety of runtime dynamics. In particular, when an event is emitted, it stores the arguments passed in transaction logs and these logs are made accessible to external analytics and reporting tools. Events can be emitted in a number of scenarios. One particular case is when system-wide parameters or settings are being changed. Another case is when tokens are being minted, transferred, or burned.

In the following, we use the GoArtCampaign contract as an example. While examining the events that reflect the GoArtCampaign dynamics, we notice there is a lack of emitting related events that reflect important state changes. Specifically, when a new admin is added or removed, when the contract state is set or the the system parameters are changed, there are no respective events being emitted to reflect the changes of the related parameters.

```
// register a new admin with the given wallet address

function addAdmin(address _adminAddress) external onlyAdmin {

// Can't add Ox address as an admin

require(_adminAddress != address(OxO), '[RBAC] : Admin must be != than OxO address')

;
```

```
84
    // Can't add existing admin
85
        require(!isAdmin[_adminAddress], '[RBAC] : Admin already exists.');
86
        // Add admin to array of admins
87
        admins.push(_adminAddress);
88
         // Set mapping
 89
        isAdmin[_adminAddress] = true;
 90
      }
91
 92
      // remove an existing admin address
93
      {\tt function \ removeAdmin(address \ \_adminAddress) \ external \ onlyAdmin \ \{}
94
        // Admin has to exist
        require(isAdmin[_adminAddress]);
 95
96
        require(admins.length > 1, 'Can not remove all admins since contract becomes
             unusable.');
97
        uint256 i = 0;
98
99
        while (admins[i] != _adminAddress) {
100
          if (i == admins.length) {
101
             revert('Passed admin address does not exist');
102
103
          i++;
104
105
106
        // Copy the last admin position to the current index
107
        admins[i] = admins[admins.length - 1];
108
109
        isAdmin[_adminAddress] = false;
110
111
        // Remove the last admin, since it's double present
112
        admins.pop();
113
      }
114
115
      // Set contract State as Active
116
      function setStateActive() external onlyAdmin {
117
        state = State.Active;
118
      }
119
120
      // Set contract State as Closed
121
      function setStateClosed() external onlyAdmin {
122
        state = State.Closed;
123
      }
124
125
      // Change the contract's max reward amount
126
      function changeMaxReward(uint256 _maxReward) external onlyAdmin {
127
         maxRewardTotal = _maxReward;
128
129
130
      // change award ration
131
      function changeRatio(uint256 _ratio) external onlyAdmin {
132
        ratio = _ratio;
133
134
```

```
// set service fee
function setServiceFee(uint256 _fee) external onlyAdmin {
   fee = _fee;
}

// set minimumAmount
function setMinimumAmount(uint256 _minimumAmount) external onlyAdmin {
   minimumAmountToWithdraw = _minimumAmount;
}
```

Listing 3.2: PresaleContract

Recommendation Properly emit the event when the related parameters are being updated.

Status This issue has been fixed in the following commit: 85011b0.

4 Conclusion

In this audit, we have analyzed the design and implementation of the RoofStacks protocol, which allow users to swap MTE points to Matic in the coin distribution web page. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Moreover, we need to emphasize that Solidity-based smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
